Theory Questions

Question 1:

Deploying an application on cloud is very different from deploying on-premises. Deploying on the cloud involves having to find a cloud service provider who is a separate entity from your company and the process will be a lot quicker and less expensive than deploying on-premises. On-premises deployment involves you needing the infrastructure to deploy the application and often it will be a lot expensive, and you will need someone who is an expert in the field to help you.

Security:

- On-premises:
The company is responsible for the security of the application and the deployment process which may be difficult for them to manage if they do not have enough expertise in their team. The company will have to make sure that the entire infrastructure is up to date and all the firmware and software that is used for the deployment system. Although there are downsides there are also positives such as it makes it more difficult to penetrate because the data centres are in house and there is very limited access especially for small companies.
- Cloud:
In cloud deployment the company will have to trust their cloud service provider to be up to date with security. The company itself does not have to worry about the security, but they do have to make sure that the cloud service provider that they choose is well equipped to handle their security. The downside to this is that is the cloud service provider is hacked then the hackers can find their way to the company through the cloud service provider.

Speed:

- On-premises:
The speed of deployment on-premises would likely take time since they would need the proper infrastructure to host and deploy the application. The team would first have to gain an understanding of what type of application they are building and what type of infrastructure they would need. After getting the infrastructure they would spend time setting it up and also configuring it for it to meet the requirements for their application. They would also have to test the infrastructure and the deployment to see if there are any problems they might run into.
- Cloud:
The speed of the deployment on the cloud would be far quicker than that of on-premises due to the fact that on the cloud the company would only need to

configure the services to suit their application, and they would be doing this online and if they are not sure they could call the cloud service provider and ask for guidance. The entire set up and configuration would be done quickly and straight after they could deploy because the cloud service provider would perform the testing for them.

Resource Management:

- On-premises:
The management of resources in on-premises needs careful planning and observation. Companies will need to monitor and predict the type of resources they will need and when they will need to upgrade their infrastructure. Due to the prices of the infrastructure such as servers, gateways, computers, companies cannot just go and buy more when they need to scale and accommodate more traffic, they often need to plan carefully what type of infrastructure they will need and how long it will last them.
- Cloud:
On cloud there is not much to manage in resources for cloud because the resources can easily be altered if they are not in use or if they need more of the certain service. The management of the resources is quite easy because you do not need any type of expertise in the field to manage it.

Question 2:

- IaaS- Infrastructure as a Service: This is a cloud hosted infrastructure for computing such as servers, storage or networking resources.
- PaaS- Platform as a Service: This is a cloud hosted platform for managing, running and developing applications.
- SaaS- Software as a Service: This is a cloud hosted application that a user will pay monthly or annually to use it; it is similar to a normal application that you can download off app stores.

The difference between all of them is that one of them is infrastructure or hardware for computing and it will be used to enhance the performance of a system, this is IaaS. The other is a platform that is used to build, run and manage applications often times it will be used by developers because it does require a level of knowledge in the field, this is PaaS. Lastly the other is a ready to use application that a user can sign up for and pay a monthly or annual fee to use the application and requires no technical knowledge because it is similar to a normal application. EventEase will benefit from PaaS because it will be easier to build using a service that already comes with frameworks and also allows developers to solely focus on the

development of the application either than the infrastructure and everything else. Paas will help the scalability of the application because there are tools inside the platform to help with the migration and improvement of the application, it provides configured environments for the life cycle of the development.
